

Background GNNs may suffer from two issues: **over-smoothing** (node features become indistinguishable with more layers) and **over-squashing** (restricted information flow via bottlenecks).

**Common approach:** Rewiring the graph by different criteria, like maximizing the spectral gap by adding edges. However, this can worsen over-smoothing, so over-squashing and over-smoothing are usually treated as opposites [1, 2].

## Main contribution

Introducing the Braess paradox: Adding extra capacity to a network can, in some cases, lead to a reduction in overall flow (and viceversa) [3, 4].

Therefore, we can find **edge deletions** that maximize the spectral gap.

Key idea: Over-smoothing and over-squashing are not a trade-off, because maximizing the spectral gap by edge deletions:

- 1. Helps reduce over-squashing, both theoretically and empirically.
- 2. Helps reduce over-smoothing, as defined in the testbed by [5] which considers node features in addition to the graph structure.

## **Proposed rewiring methods**

- EldanAdd/EldanDelete: Based on a lemma by [4] that states a sufficient condition for the Braess paradox to occur.
- 2. **ProxyAdd/ProxyDelete**: Better and constant-time approximation of  $\lambda$  usin matrix perturbation theory [6, 7]:

$$\dot{\lambda} \approx \lambda + \Delta w_{u,v}((f_u - f_v)^2 - \lambda (f_u^2 + f_v^2))$$

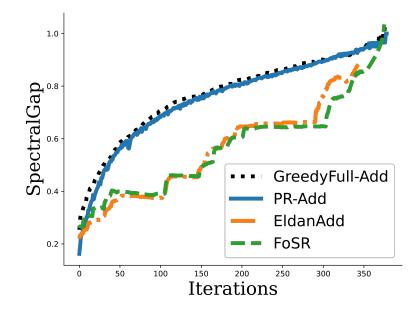

Table 1. Runtimes (in seconds) for 50 edge modifications.

- 1. Over-smoothing and over-squashing are **not necessarily diametrically opposed**: both can be mitigated by spectral based edge deletions.
- 2. We propose a greedy graph pruning algorithm that maximizes the spectral gap in a computationally efficient way. It can also be utilized to add edges.
- 3. We **connect literature** on three seemingly disconnected topics: over-smoothing, over-squashing, and graph lottery tickets.
